# Integer Linear Programming

## General Model:

$$\max / \min : z = \sum_{j=1}^n c_j x_j \quad (1.1)$$

subject to

$$\sum_{j=1}^n a_{ij} x_j (\leq = \geq) b_i, \quad i = 1, 2, \dots, m \quad (1.2)$$

$$x_j = 0, 1, 2, 3, \dots \quad j = 1, 2, \dots, n \quad (1.3)$$

where  $c_j$ ,  $a_{ij}$  and  $b_i$  are integers.

## Cutting Plane method

### Cutting Plane method of Gomory (1958)

At first an Integer Programming Problem is solved as a regular LPP by dropping the integral condition. If the optimal solution ( $x^*$ ) happens to be integer, terminate the process.

Otherwise, the secondary constrained will be added that will force the solution toward the integer solution. These constraints can be developed as follows:

## Cutting Plane method(cont.)

Let the optimal Tableau for the LPP be given by:

$C_B$	BV \ NBV	$w_1$	$w_2$	$\dots$	$w_j$	$\dots$	$w_n$	$X_B$
*	$x_1$	$\alpha_{11}$	$\alpha_{12}$	$\dots$	$\alpha_{1j}$	$\dots$	$\alpha_{1n}$	$\beta_1$
*	$x_2$	$\alpha_{21}$	$\alpha_{22}$	$\dots$	$\alpha_{2j}$	$\dots$	$\alpha_{2n}$	$\beta_2$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\dots$	$\vdots$	$\dots$	$\vdots$	$\vdots$
*	$x_i$	$\alpha_{i1}$	$\alpha_{i2}$	$\dots$	$\alpha_{ij}$	$\dots$	$\alpha_{in}$	$\beta_i$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\dots$	$\vdots$	$\dots$	$\vdots$	$\vdots$
*	$x_m$	$\alpha_{m1}$	$\alpha_{m2}$	$\dots$	$\alpha_{mj}$	$\dots$	$\alpha_{mn}$	$\beta_m$
		$\overline{z_1 - c_1}$	$\overline{z_2 - c_2}$	$\dots$	$\overline{z_j - c_j}$	$\dots$	$\overline{z_n - c_n}$	$\overline{z}$

where  $\overline{z_j - c_j} \geq 0, \quad j = 1, 2, \dots, n.$

$x_i$  ( $i = 1, 2, \dots, m$ ) is the  $i$ -th basic variable

$w_j$  ( $j = 1, 2, \dots, n$ ) is the  $j$ -th non-basic variable

## Cutting Plane method(cont.)

Let  $x_i$  be non-integer. Its value  $\beta_i$  has the largest fractional part. i.e.,

$$x_i + \sum_{j=1}^n \alpha_{ij} w_j = \beta_i, \quad \beta_i > 0$$

where  $\beta_i = [\beta_i] + f_i$ ,  $0 < f_i < 1$  and  $\alpha_{ij} = [\alpha_{ij}] + f_{ij}$ ,  $0 \leq f_{ij} < 1$

**Example:**  $[k] \leq k$  : greatest integer function

$$[2\frac{1}{2}] = 2 \Rightarrow \frac{1}{2} + 2 = 2\frac{1}{2}$$

$$[-3\frac{1}{2}] = -4 \Rightarrow \frac{1}{2} - 4 = -3\frac{1}{2}$$

$$[5] = 5$$

$$[-5] = -5 \text{ etc}$$

## Cutting Plane method(cont.)

Now,

$$x_i + \sum_{j=1}^n ([\alpha_{ij}] + f_{ij}) w_j = [\beta_i] + f_i$$
$$\Rightarrow x_i - [\beta_i] + \sum_{j=1}^n [\alpha_{ij}] w_j = f_i - \sum_{j=1}^n f_{ij} w_j$$

For all  $x_i, w_j$  LHS is an integer. Hence RHS is an integer.

But  $f_i - \sum_{j=1}^n f_{ij} w_j \leq f_i < 1$  an integer.

## Cutting Plane method(cont.)

Therefore,

$$f_i - \sum_{j=1}^n f_{ij} w_j \leq 0$$

$$\Rightarrow \sum_{j=1}^n f_{ij} w_j \geq f_i$$

$$\Rightarrow - \sum_{j=1}^n f_{ij} w_j \leq -f_i$$

$$\Rightarrow - \sum_{j=1}^n f_{ij} w_j + s_i = -f_i$$

This fractional cut may be added to the last simplex Tableau. The problem may be solved by Dual Simplex method. This procedure is repeated till we find an integer solution.

$$\max / \min : Z = \sum_{j=1}^n c_j x_j \quad (1.4)$$

subject to

$$\sum_{j=1}^n a_{ij} x_j (\leq = \geq) b_i, \quad i = 1, 2, \dots, m \quad (1.5)$$

$$x_j = 0, 1, 2, 3, \dots \quad j = 1, 2, \dots, n \quad (1.6)$$

where the cost coefficients  $c_j$ , technological coefficients  $a_{ij}$  and target value  $b_i$  are integers for  $i = 1, 2, \dots, m; j = 1, 2, \dots, n$ .

## Branch and Bound Method (cont.)

- Solve the Integer Programming problem by graphical method (2D)/ Simplex method by dropping integer restrictions.
- Let  $x_j$  be an integer variable whose optimal value  $x_j^*$  is fractional. Then the range

$$[x_j^*] < x_j < [x_j^*] + 1$$

can not include any solution which is integer.

- A feasible integral value of  $x_j$  must satisfy either

$$x_j \geq [x_j^*] + 1 \quad (1.7)$$

or

$$x_j \leq [x_j^*] \quad (1.8)$$

## Branch and Bound Method (cont.)

- By imposing the constraints (2.7) and (2.8) to the original LPP we find two mutually exclusive LP Problems.
- Hence the problem is branched into two subproblems. The optimal value of the objective function  $Z$  for the non-integer case be  $Z^*$ .
- For the integer case (discrete case) the optimal value  $Z^*$  is  $\leq [Z^*]$ . It is a bound (upper bound) for the objective function.
- This procedure is to be repeated a number of times to find an all integer solution  $x^*$
